## Overview

What is an energy storage system?

An energy storage system (ESS) for electricity generation uses electricity (or some other energy source, such as solar-thermal energy) to charge an energy storage system or device, which is discharged to supply (generate) electricity when needed at desired levels and quality. ESSs provide a variety of services to support electric power grids.

Why is there no work done on the system?

There is no work done on the system because all the forces are contained in the system. What does it mean?

Since The Law of Conservation of Energy states energy cannot be created or destroyed, this means that the total energy in the universe is constant and does not change in value, assuming there is nothing beyond the universe.

How does energy storage work?

The so-called battery “charges” when power is used to pump water from a lower reservoir to a higher reservoir. The energy storage system “discharges” power when water, pulled by gravity, is released back to the lower-elevation reservoir and passes through a turbine along the way.

What is the difference between an isolated system and a non isolated system?

This only applies to isolated systems (no outside forces acting on the system).  
Not Isolated: An object sliding across a rough floor (system = the object). There is work being done by the floor on the object because of the frictional force. Energy lost to heat due to friction is an example of mechanical energy being converted into thermal energy.

Remember, the law of conservation of energy applies to a closed system. Sometimes it isn't easy or even possible to define or isolate a system. This comes into play in general relativity, where systems don't always have time translation symmetry. For example, conservation of energy isn't necessarily defined for curved spacetime or time crystals.
